

Noisy Channel and Hidden Markov Models

Natural Language Processing
CS 6120—Spring 2014
Northeastern University

David Smith
with material from Jason Eisner & Andrew McCallum

Warren Weaver
to Norbert Wiener
4 March 1947

One thing I wanted to ask you about is this. A most serious problem, for UNESCO and for the constructive and peaceful future of the planet, is the problem of translation, as it unavoidably affects the communication between peoples. Huxley has recently told me that they are appalled by the magnitude and the importance of the translation job.

Recognizing fully, even though necessarily vaguely, the semantic difficulties because of multiple meanings, etc., I have wondered if it were unthinkable to design a computer which would translate. Even if it would translate only scientific material (where the semantic difficulties are very notably less), and even if it did produce an inelegant (but intelligible) result, it would seem to me worth while.

Also knowing nothing official about, but having guessed and inferred considerable about, powerful new mechanized methods in cryptography—methods which I believe succeed even when one does not know what language has been coded—one naturally wonders if the problem of translation could conceivably be treated as a problem in cryptography. When I look at an article in Russian, I say: “This is really written in English, but it has been coded in some strange symbols. I will now proceed to decode.”

Word Segmentation

theprophetsaidtothecity

- What does this say?
 - And what other words are substrings?
- Given L = a "lexicon" FSA that matches all English words.
- How to apply to this problem?
- What if Lexicon is weighted?
- From unigrams to bigrams?
- Smooth L to include unseen words?

Spelling correction

- Spelling correction also needs a lexicon L
- But there is distortion ...
 - Let T be a transducer that models common typos and other spelling errors
 - $\text{ance} \rightarrow \text{ence}$ (deliverance, ...)
 - $e \rightarrow \varepsilon$ (deliverance, ...)
 - $\varepsilon \rightarrow e$ // Cons _ Cons (athlete, ...)
 - $rr \rightarrow r$ (embarrass occurrence, ...)
 - $ge \rightarrow dge$ (privilege, ...)
 - etc.
 - Now what can you do with L .o. T ?
- Should T and L have probabilities?
- Want T to include “all possible” errors ...

Morpheme Segmentation

- Let Lexicon be a machine that matches all Turkish words
 - Same problem as word segmentation (in, e.g., Chinese)
 - Just at a lower level: morpheme segmentation
 - Turkish word: **uygarlaştıramadıklarımızdanmışsınızcasına**
= **uygar+laş+tır+ma+dık+ları+mız+dan+miş+sınız+ca+sı+na**
(behaving) as if you are among those whom we could not cause to become civilized
 - Some constraints on morpheme sequence: bigram probs
 - Generative model – concatenate then fix up joints
 - stop + -ing = stop**ing**, fly + -s = fl**ies**, vowel harmony
 - Use a cascade of transducers to handle all the fixups
 - But this is just morphology!
 - Can use probabilities here too (but people often don't)

The Tagging Task

The Tagging Task

Input: the lead paint is unsafe

The Tagging Task

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

The Tagging Task

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

The Tagging Task

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- **Uses:**

The Tagging Task

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- **Uses:**
 - text-to-speech (how do we pronounce “lead”?)

The Tagging Task

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- **Uses:**
 - text-to-speech (how do we pronounce “lead”?)
 - can write regexps like (Det) Adj* N+ over the output

The Tagging Task

Input: `the lead paint is unsafe`

Output: `the/Det lead/N paint/N is/V unsafe/Adj`

- **Uses:**
 - text-to-speech (how do we pronounce “lead”?)
 - can write regexps like `(Det) Adj* N+` over the output
 - preprocessing to speed up parser (but a little dangerous)

The Tagging Task

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- **Uses:**

- text-to-speech (how do we pronounce “lead”?)
- can write regexps like `(Det) Adj* N+` over the output
- preprocessing to speed up parser (but a little dangerous)
- if you know the tag, you can back off to it in other tasks

Why Do We Care?

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

Why Do We Care?

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- The first statistical NLP task

Why Do We Care?

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- The first statistical NLP task
- Been done to death by different methods

Why Do We Care?

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- The first statistical NLP task
- Been done to death by different methods
- Easy to evaluate (how many tags are correct?)

Why Do We Care?

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- The first statistical NLP task
- Been done to death by different methods
- Easy to evaluate (how many tags are correct?)
- Canonical finite-state task (in English)

Why Do We Care?

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- The first statistical NLP task
- Been done to death by different methods
- Easy to evaluate (how many tags are correct?)
- Canonical finite-state task (in English)
 - Can be done well with methods that look at local context

Why Do We Care?

Input: the lead paint is unsafe

Output: the/Det lead/N paint/N is/V unsafe/Adj

- The first statistical NLP task
- Been done to death by different methods
- Easy to evaluate (how many tags are correct?)
- Canonical finite-state task (in English)
 - Can be done well with methods that look at local context
 - Though should “really” do it by parsing!

Tagged Data Sets

- Brown Corpus
 - Designed to be a representative sample from 1961
 - news, poetry, “belles lettres”, short stories
 - 87 different tags
- Penn Treebank
 - 45 different tags
 - Currently most widely used for English
- Now a paradigm in lots of other languages
 - Chinese Treebank has over 200 tags

Penn Treebank POS Tags

<u>PART-OF-SPEECH</u>	<u>TAG</u>	<u>EXAMPLES</u>
• Adjective	JJ	happy, bad
• Adjective, comparative	JJR	happier, worse
• Adjective, cardinal number	CD	3, fifteen
• Adverb	RB	often, particularly
• Conjunction, coordination	CC	and, or
• Conjunction, subordinating	IN	although, when
• Determiner	DT	this, each, other, the, a, some
• Determiner, postdeterminer	JJ	many, same
• Noun	NN	aircraft, data
• Noun, plural	NNS	women, books
• Noun, proper, singular	NNP	London, Michael
• Noun, proper, plural	NNPS	Australians, Methodists
• Pronoun, personal	PRP	you, we, she, it
• Pronoun, question	WP	who, whoever
• Verb, base present form	VBP	take, live

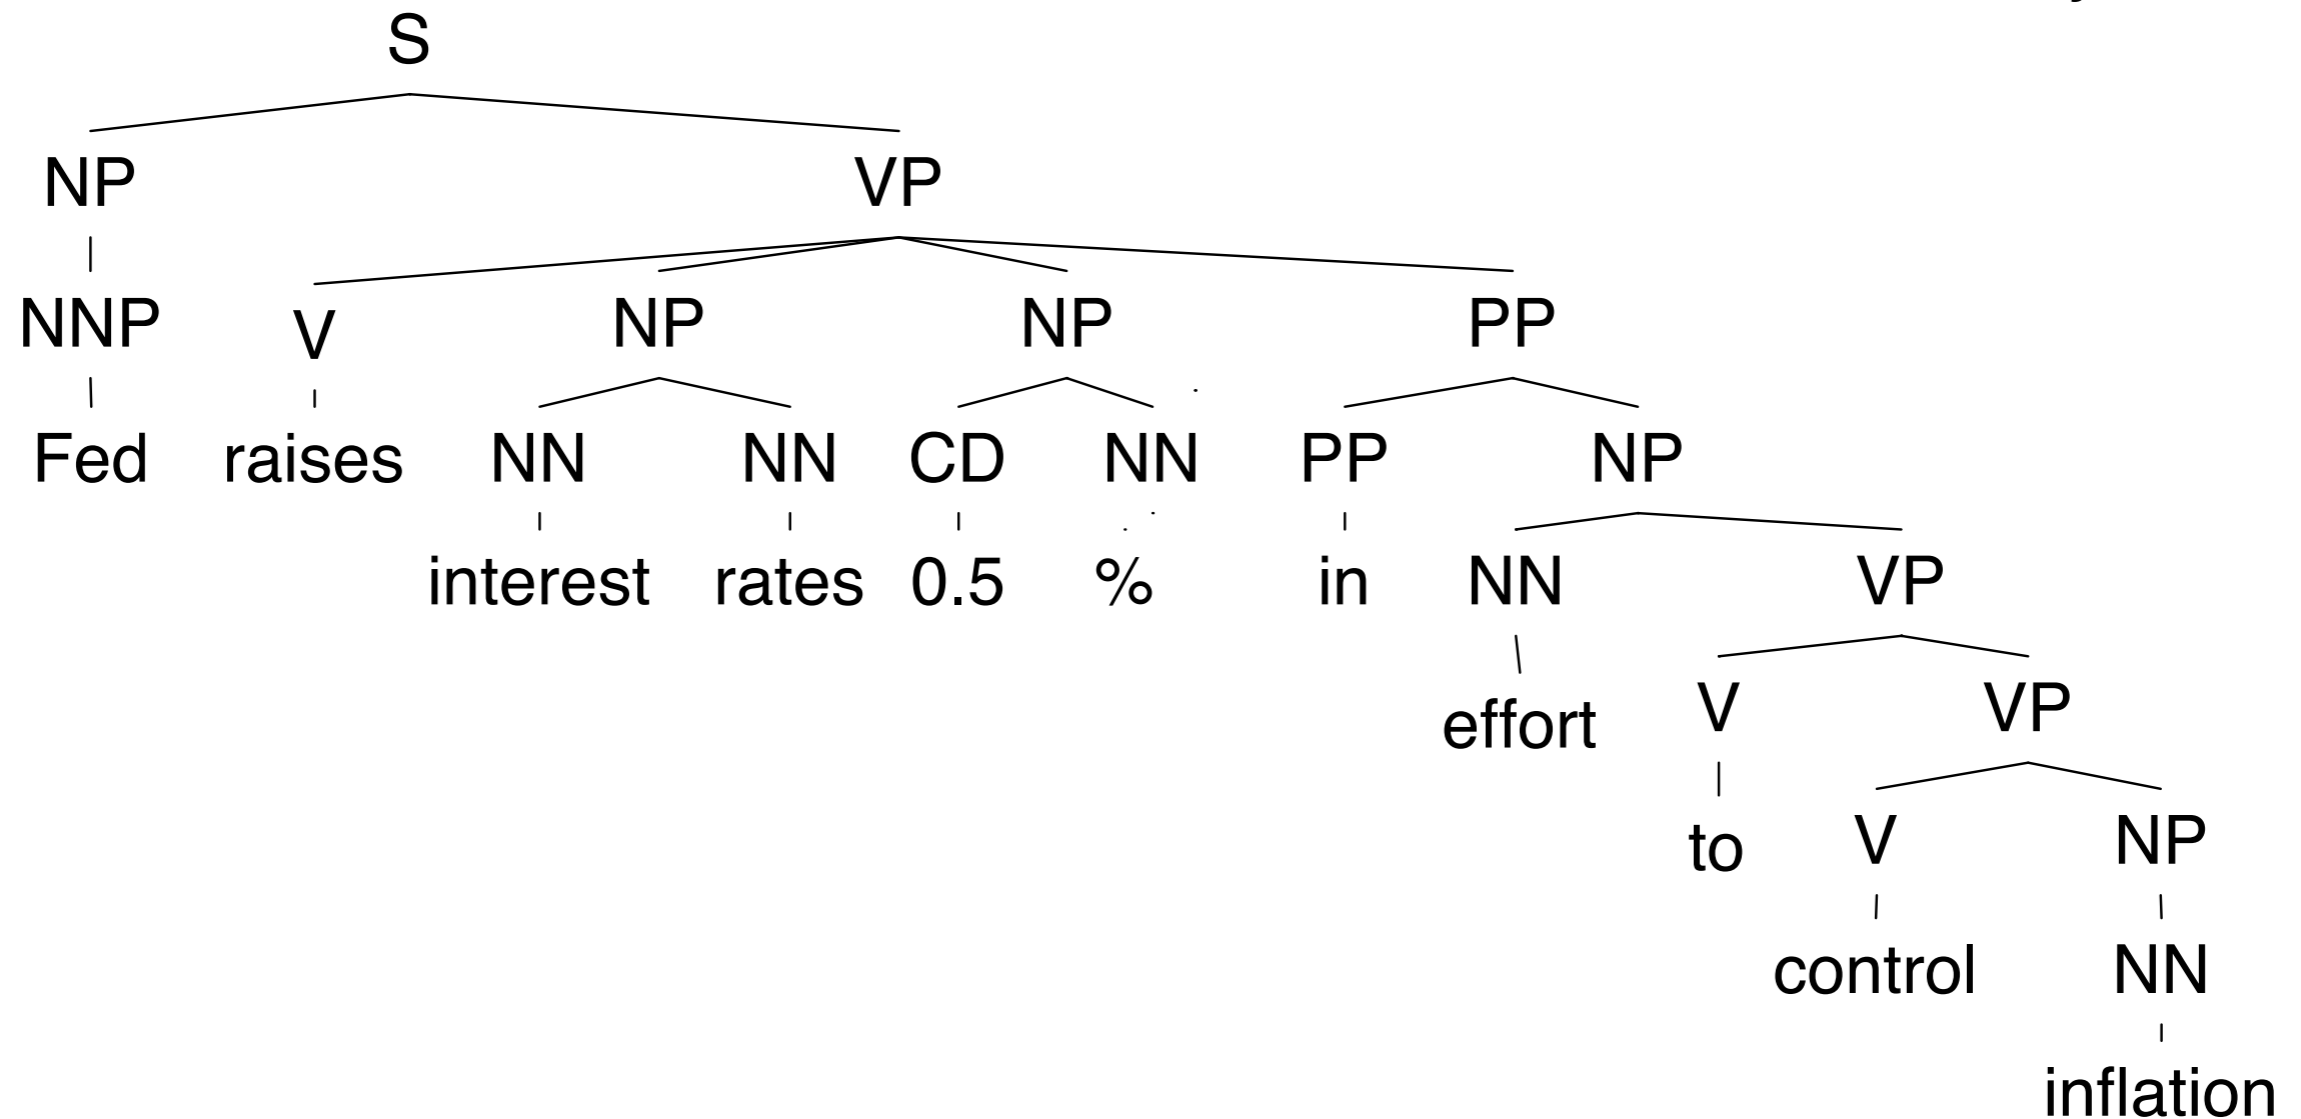

Word Class Classes

- Importantly for predicting POS tags, there are two broad classes
- “Closed class” words
 - Belong to classes that don’t accept new members
 - Determiners: the, a, an, this, ...
 - Prepositions: in, on, of, ...
- “Open class” words
 - Nouns, verbs, adjectives, adverbs, ...
- “Closed” is relative: These words are born and die over longer time scales (e.g, “regarding”)

Find best path from Start to Stop

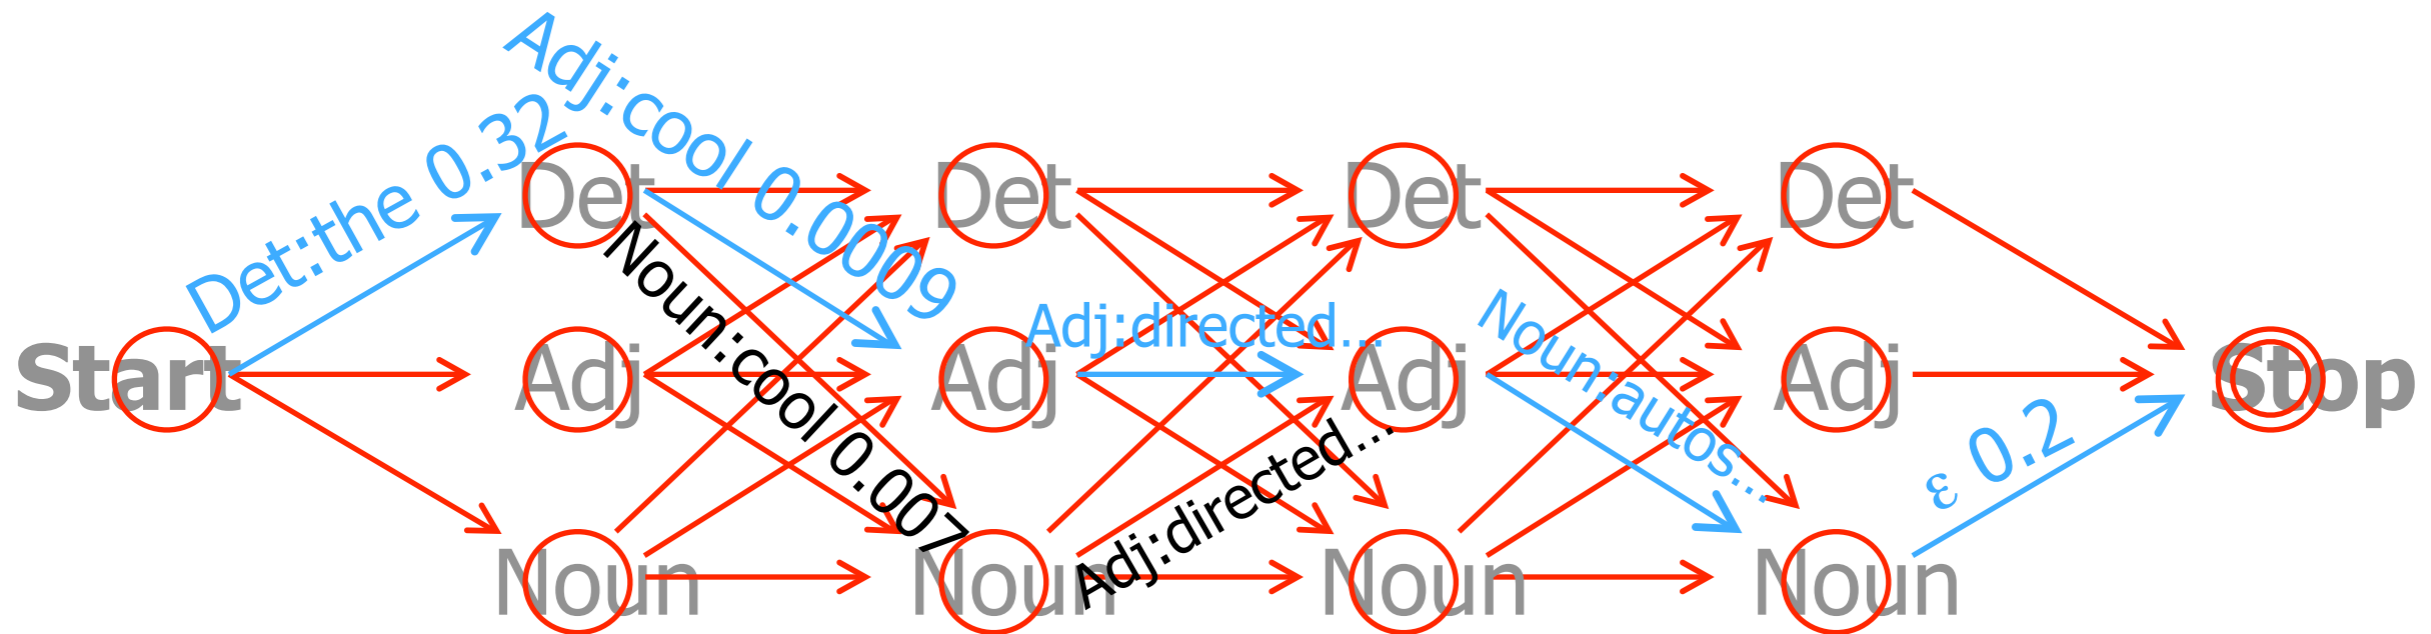

Find best path from Start to Stop

- Use dynamic programming:
 - What is best path from Start to each node?
 - Work from left to right
 - Each node stores its best path from Start (as probability plus one backpointer)

Find best path from Start to Stop

- Use dynamic programming:
 - What is best path from Start to each node?
 - Work from left to right
 - Each node stores its best path from Start (as probability plus one backpointer)
- Special acyclic case of Dijkstra's shortest-path alg.

Find best path from Start to Stop

- Use dynamic programming:
 - What is best path from Start to each node?
 - Work from left to right
 - Each node stores its best path from Start (as probability plus one backpointer)
- Special acyclic case of Dijkstra's shortest-path alg.
- Faster if some arcs/states are absent

In Summary

Standard View of HMMs

Applications of HMMs

- NLP
 - Part-of-speech tagging
 - Word segmentation
 - Information extraction
 - Optical character recognition
- Speech recognition
 - Modeling acoustics, with continuous emissions
- Computer Vision
 - Gesture recognition
- Biology
 - Gene finding
 - Protein structure prediction
- Economics, Climatology, Robotics, etc.

Recipe for NLP

Input: the lead paint is unsafe Observations

Output: the/Det lead/N paint/N is/V unsafe/Adj Tags

- 1) **Data:** Notation, representation
- 2) **Problem:** Write down the problem in notation
- 3) **Model:** Make some assumptions, define a parametric model (often generative model of the data)
- 4) **Inference:** How to search through possible answers to find the best one
- 5) **Learning:** How to estimate parameters
- 6) **Implementation:** Engineering considerations for an efficient implementation

An HMM Tagger

- View sequence of tags as a Markov chain.

Assumptions:

- Limited horizon $P(x_{t+1}|x_1, \dots, x_t) = P(x_{t+1}|x_t)$
- Time invariant (stationary) $P(x_{t+1}|x_t) = P(x_2|x_1)$
- We assume that a word's tag only depends on the previous tag (limited horizon) and that his dependency does not change over time (time invariance)
- A state (part of speech) generates a word. We assume it depends only on the state.

$$P(o_t|x_1, \dots, x_T, o_1, \dots, o_{t-1}) = P(o_t|x_t)$$

The Markov Property

- A stochastic process has the **Markov property** if the conditional probability distribution of future states of the process, given the current state, depends only upon the current state, and conditionally independent of the past states (the *path* of the process) given the current state.
- A process with the Markov property is usually called a **Markov process**, and may be described as *Markovian*.

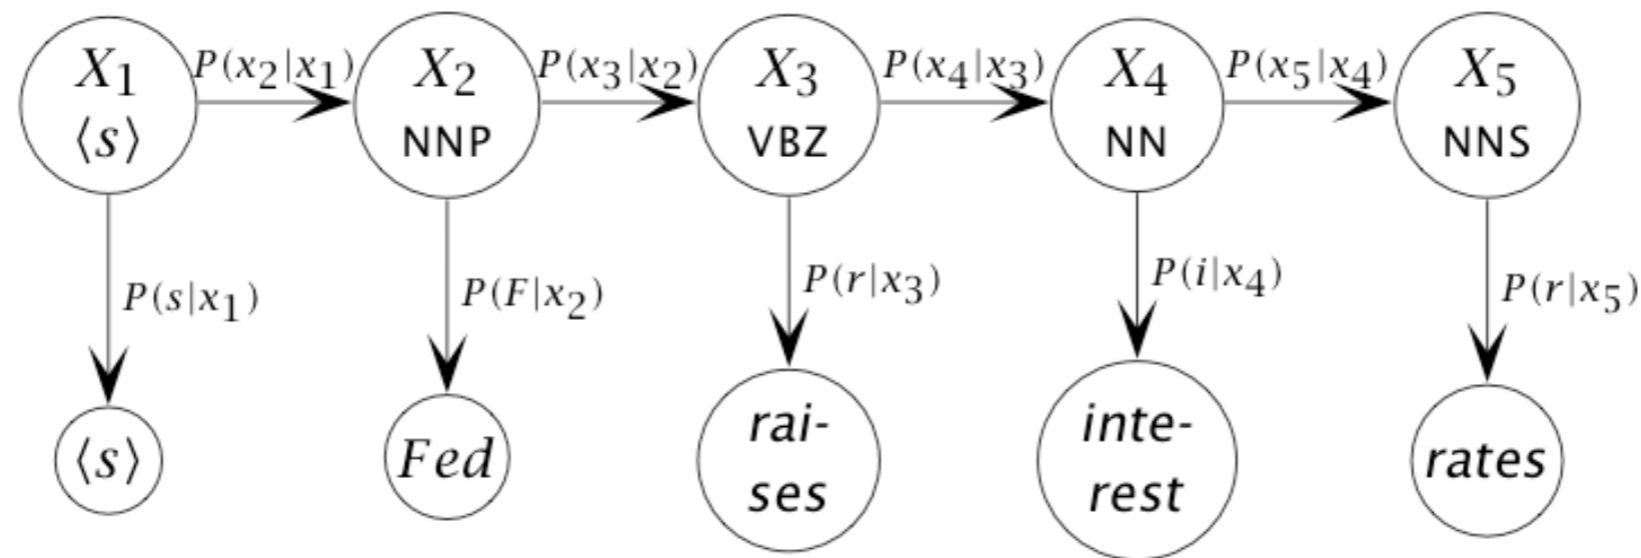

$$\Pr[X(t+h) = y \mid X(s) = x(s), s \leq t] = \Pr[X(t+h) = y \mid X(t) = x(t)], \quad \forall h > 0.$$

HMM w/State Emissions

transitions

HMM as Bayes Net

- Top row is unobserved states, interpreted as POS tags
- Bottom row is observed output observations (words)

(One) Standard HMM Formalism

- (X, O, x_s, A, B) are all variables. Model $\mu = (A, B)$
- X is state sequence of length T ; O is observation seq.
- x_s is a designated start state (with no incoming transitions). (Can also be separated into π as in book.)
- A is matrix of transition probabilities (each row is a conditional probability table (CPT))
- B is matrix of output probabilities (vertical CPTs)

$$P(X, O|\mu) = \prod_{t=1}^T a[x_t|x_{t-1}] b[o_t|x_t]$$

- HMM is a probabilistic (nondeterministic) finite state automaton, with probabilistic outputs (from vertices, not arcs, in the simple case)

HMM Inference Problems

- Given an observation sequence, find the most likely state sequence (**tagging**)
- Compute the probability of observations when state sequence is hidden (**language modeling**)
- Given observations and (optionally) a their corresponding states, find parameters that maximize the probability probability of the observations (**parameter estimation**)

Most Likely State Sequence

- Given $O = (o_1, \dots, o_T)$ and model $\mu = (A, B)$
- We want to find

$$\arg \max_X P(X|O, \mu) = \arg \max_X \frac{P(X, O|\mu)}{P(O|\mu)} = \arg \max_X P(X, O|\mu)$$

- $P(O, X|\mu) = P(O|X, \mu) P(X|\mu)$
- $P(O|X, \mu) = b[x_1|o_1] b[x_2|o_2] \dots b[x_T|o_T]$
- $P(X|\mu) = a[x_1|x_2] a[x_2|x_3] \dots a[x_{T-1}|x_T]$
- $\arg \max_X P(O, X|\mu) = \arg \max_{x_1, x_2, \dots, x_T}$
- Problem: arg max is exponential in sequence length!

Paths in a Trellis

Paths in a Trellis

Paths in a Trellis

$\delta_i(t)$ = Probability of most likely path that ends at state i at time t .

Dynamic Programming

- Efficient computation of max over all states
- Intuition: Probability of the first t observations is the same for all possible $t+1$ length sequences.

- Define forward score:

$$\delta_i(t) = \max_{x_1 \dots x_{t-1}} P(o_1 o_2 \dots o_t, x_1 \dots x_{t-1}, x_t = i | \mu)$$

$$\delta_j(t+1) = \max_{i=1..N} \delta_i(t) a[x_j | x_i] b[o_{t+1} | x_j]$$

- Compute it recursively from the beginning
- (Then must remember best paths to get arg max.)

The Viterbi Algorithm (1967)

- Used to efficiently find the state sequence that gives the highest probability to the observed outputs
- Maintains two dynamic programming tables:

- The probability of the best path (max)

$$\delta_j(t+1) = \max_{i=1..N} \delta_i(t) a[x_j|x_i] b[o_{t+1}|x_j]$$

- The state transitions of the best path (arg)

$$\psi_j(t+1) = \arg \max_{i=1..N} \delta_i(t) a[x_j|x_i] b[o_{t+1}|x_j]$$

- Note that this is different from finding the most likely tag for each time t !

Viterbi Recipe

- Initialization

$$\delta_j(0) = 1 \text{ if } x_j = x_s. \quad \delta_j(0) = 0 \text{ otherwise.}$$

- Induction

$$\delta_j(t+1) = \max_{i=1..N} \delta_i(t) a[x_j|x_i] b[o_{t+1}|x_j]$$

Store backtrace

$$\psi_j(t+1) = \arg \max_{i=1..N} \delta_i(t) a[x_j|x_i] b[o_{t+1}|x_j]$$

- Termination and path readout

$$\hat{x}_T = \arg \max_{i=1..N} \delta_i(T)$$

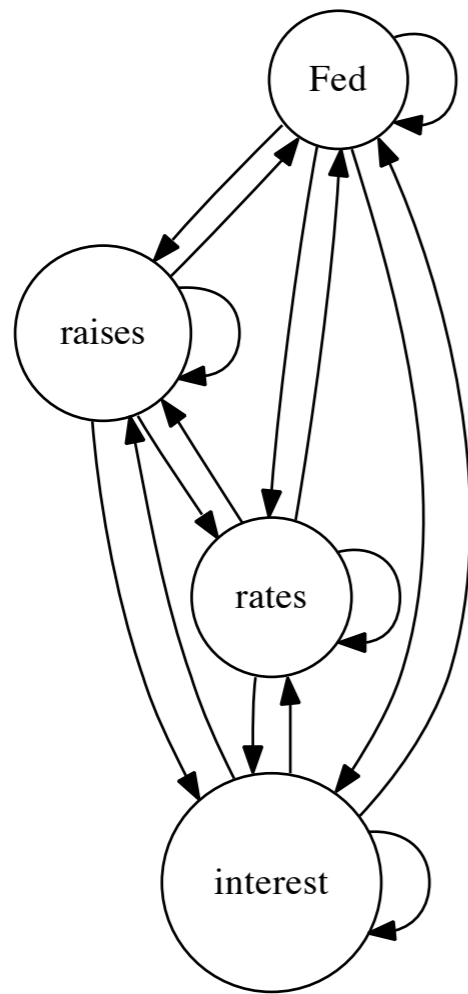

Probability of entire best seq.

$$\hat{x}_t = \psi_{\hat{x}_{t+1}}(t+1)$$

$$P(\hat{X}) = \max_{i=1..N} \delta_i(T)$$

HMM Inference Problems

- Given an observation sequence, find the most likely state sequence (**tagging**)
- Compute the probability of observations when state sequence is hidden (**language modeling**)
- Given observations and (optionally) a their corresponding states, find parameters that maximize the probability probability of the observations (**parameter estimation**)

Tagging

Given an observation sequence, find the most likely state sequence.

$$\arg \max_X P(X | O, \mu) = \arg \max_X \frac{P(X, O | \mu)}{P(O | \mu)} = \arg \max_X P(X, O | \mu)$$

$$\arg \max_{x_1, x_2, \dots, x_T} P(x_1, x_2, \dots, x_T, O | \mu)$$

Last time: Use dynamic programming to find highest-probability sequence (i.e. best path, like Dijkstra's algorithm)

Language Modeling

Compute the probability of observations when state sequence is hidden.

$$P(X, O \mid \mu) = P(O \mid X, \mu)P(X \mid \mu)$$

Therefore

$$P(O \mid \mu) = \sum_X P(O \mid X, \mu)P(X \mid \mu)$$

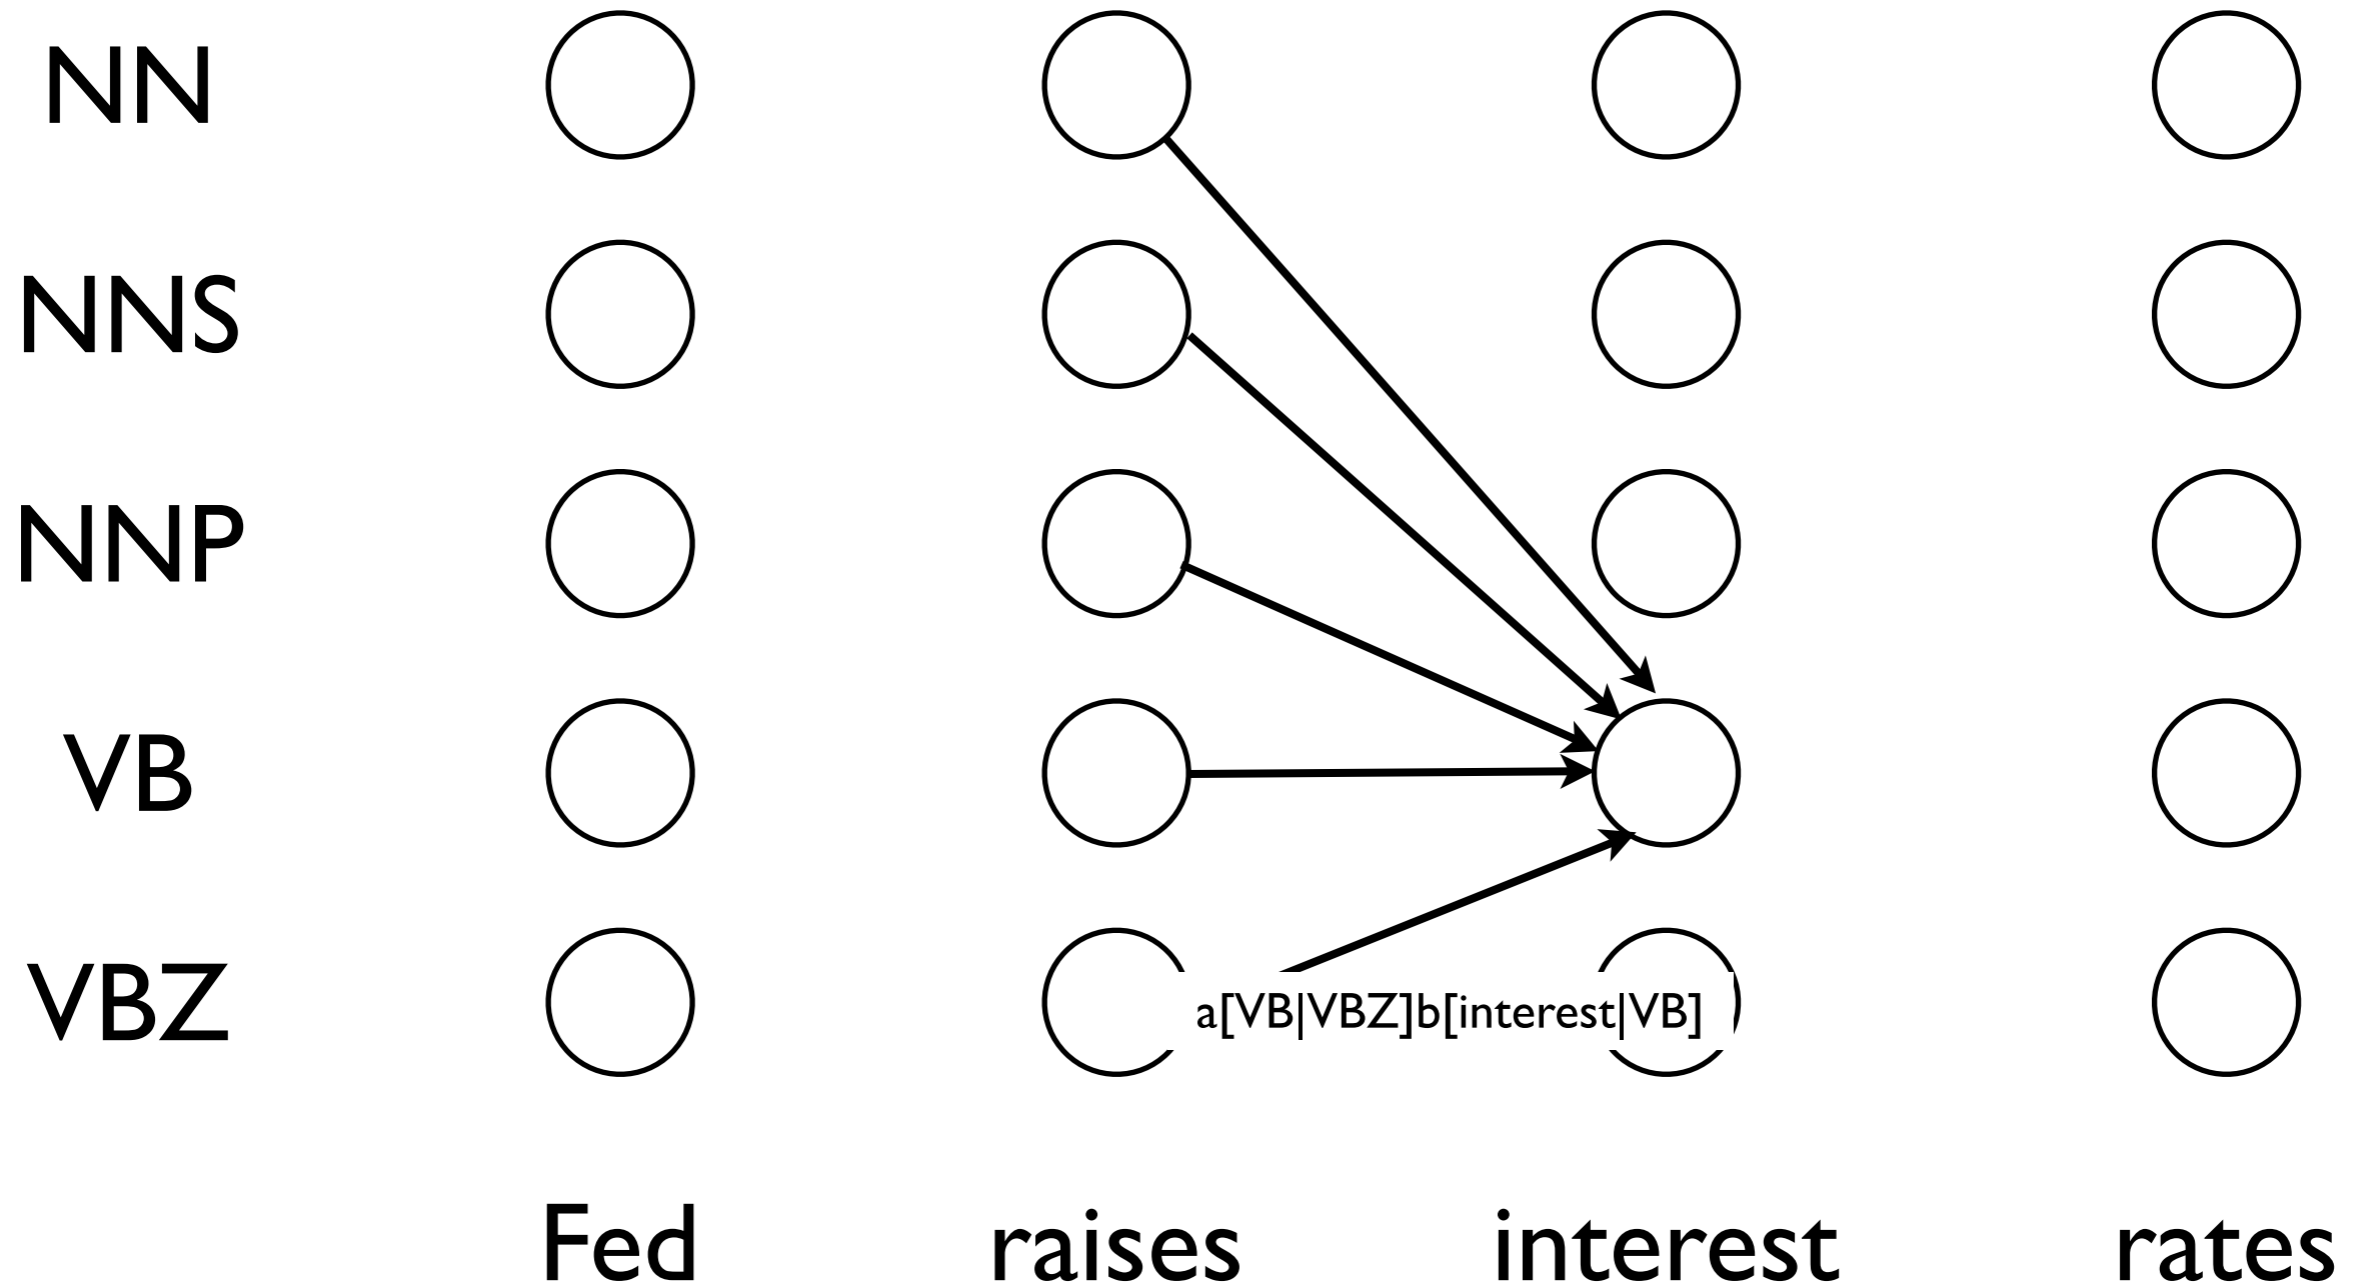

$$\sum_{x_1, x_2, \dots, x_T} P(x_1, x_2, \dots, x_T, O \mid \mu)$$

Suspiciously similar to $\max_{x_1, x_2, \dots, x_T} P(x_1, x_2, \dots, x_T, O \mid \mu)$

NOT
the probability of tag
at time

HMM Language Modeling

- Probability of observations, summed over all possible ways of tagging that

observation:

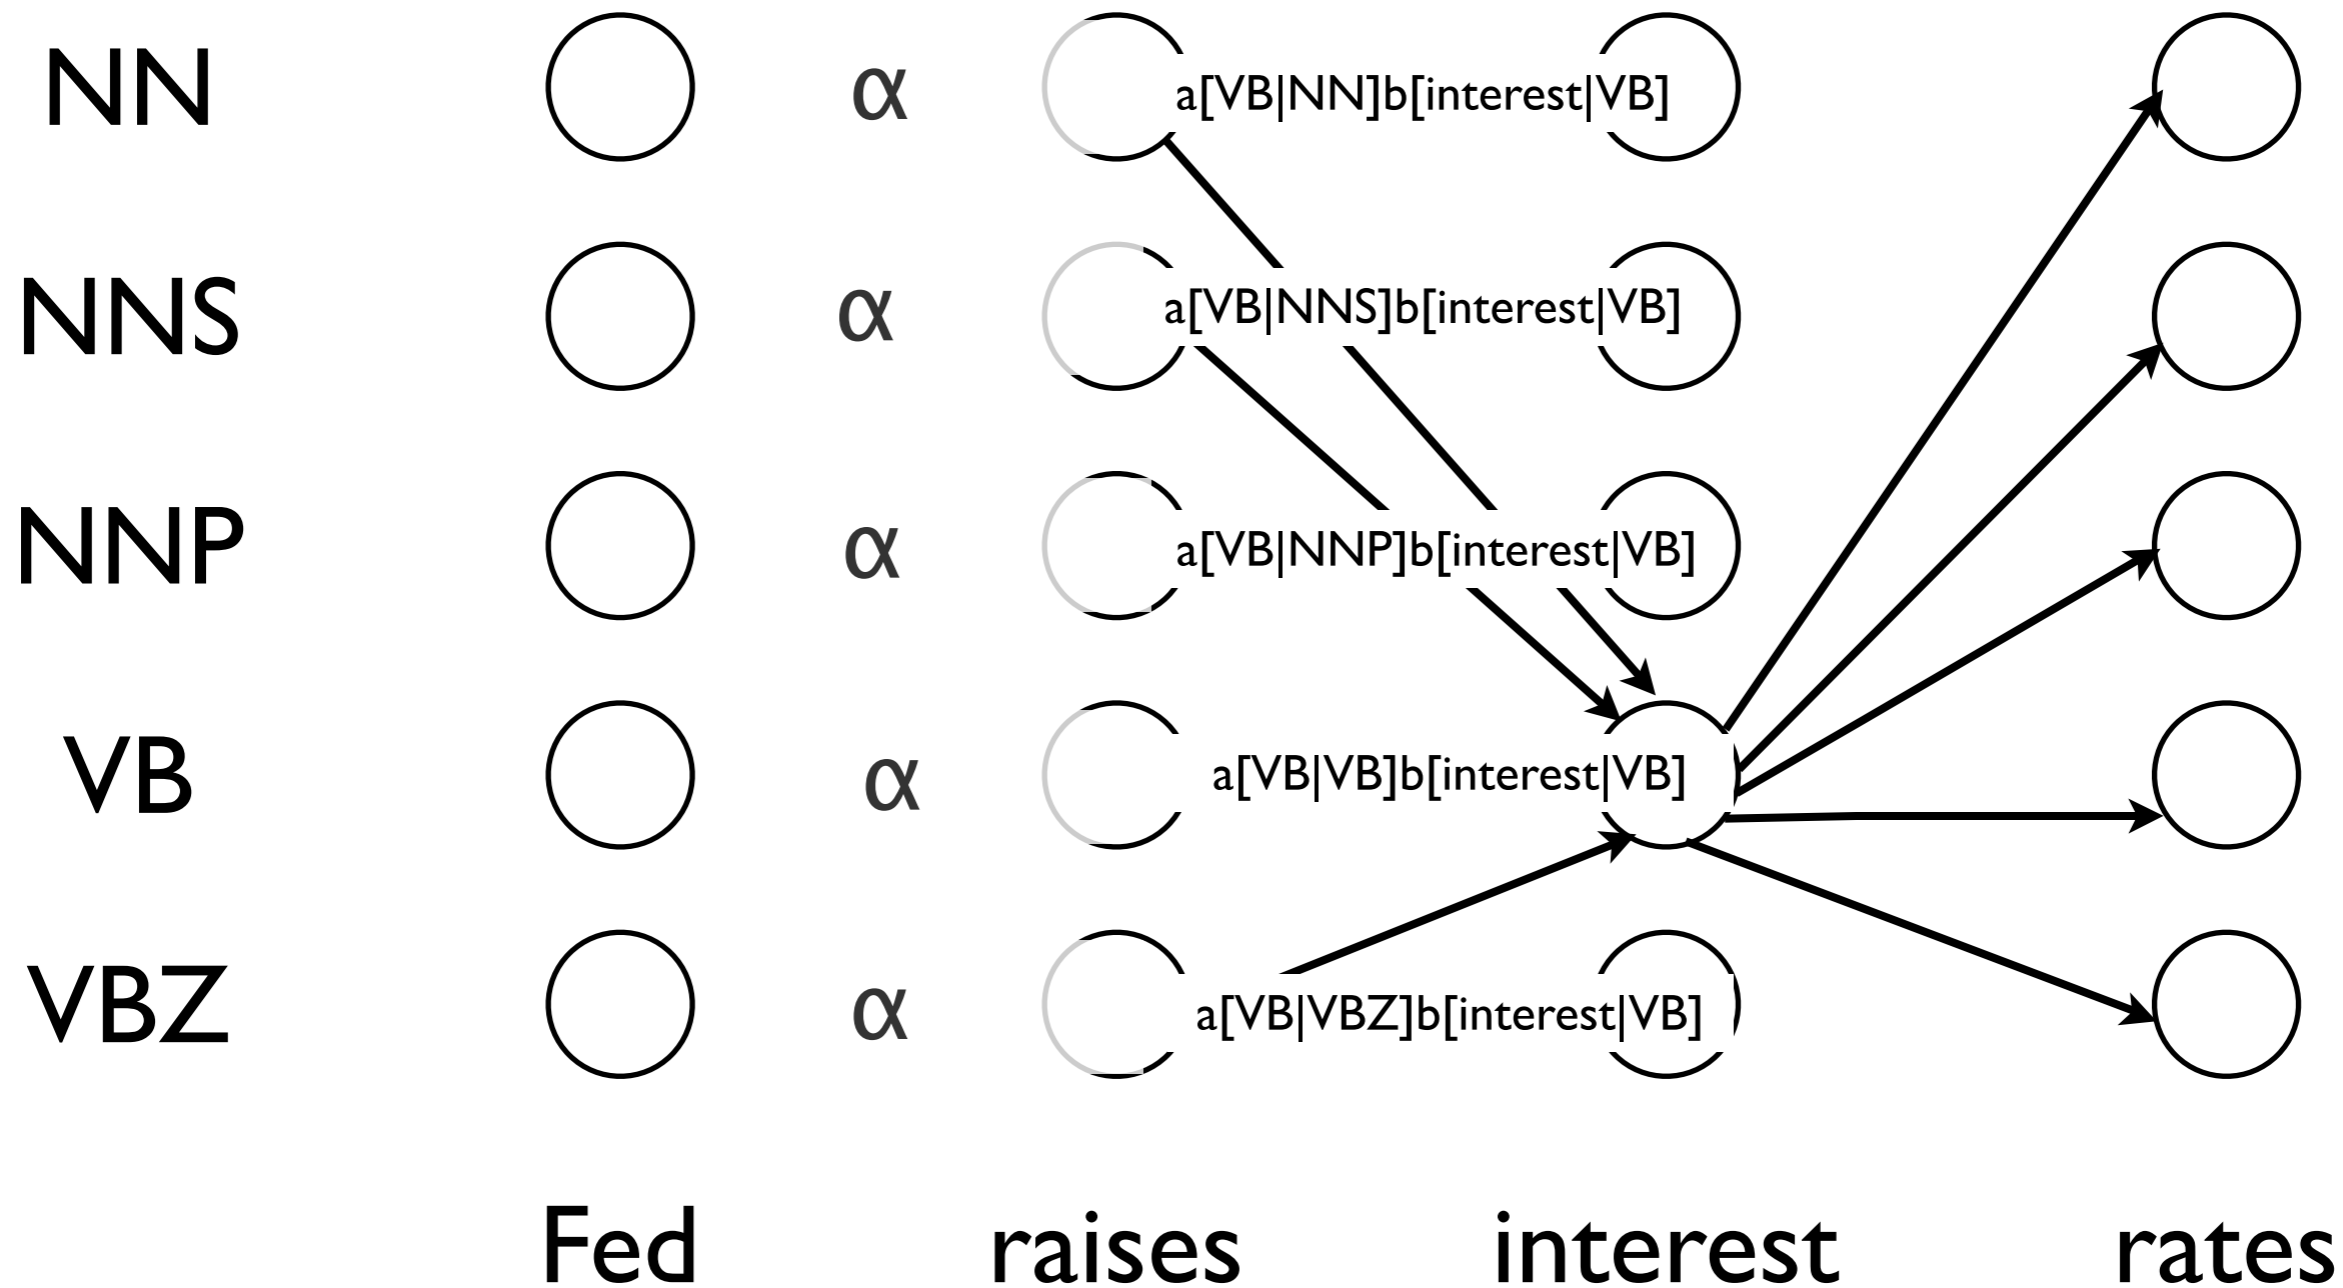

$$\sum_i \alpha_i(T)$$

- This is the sum of all path probabilities in the trellis

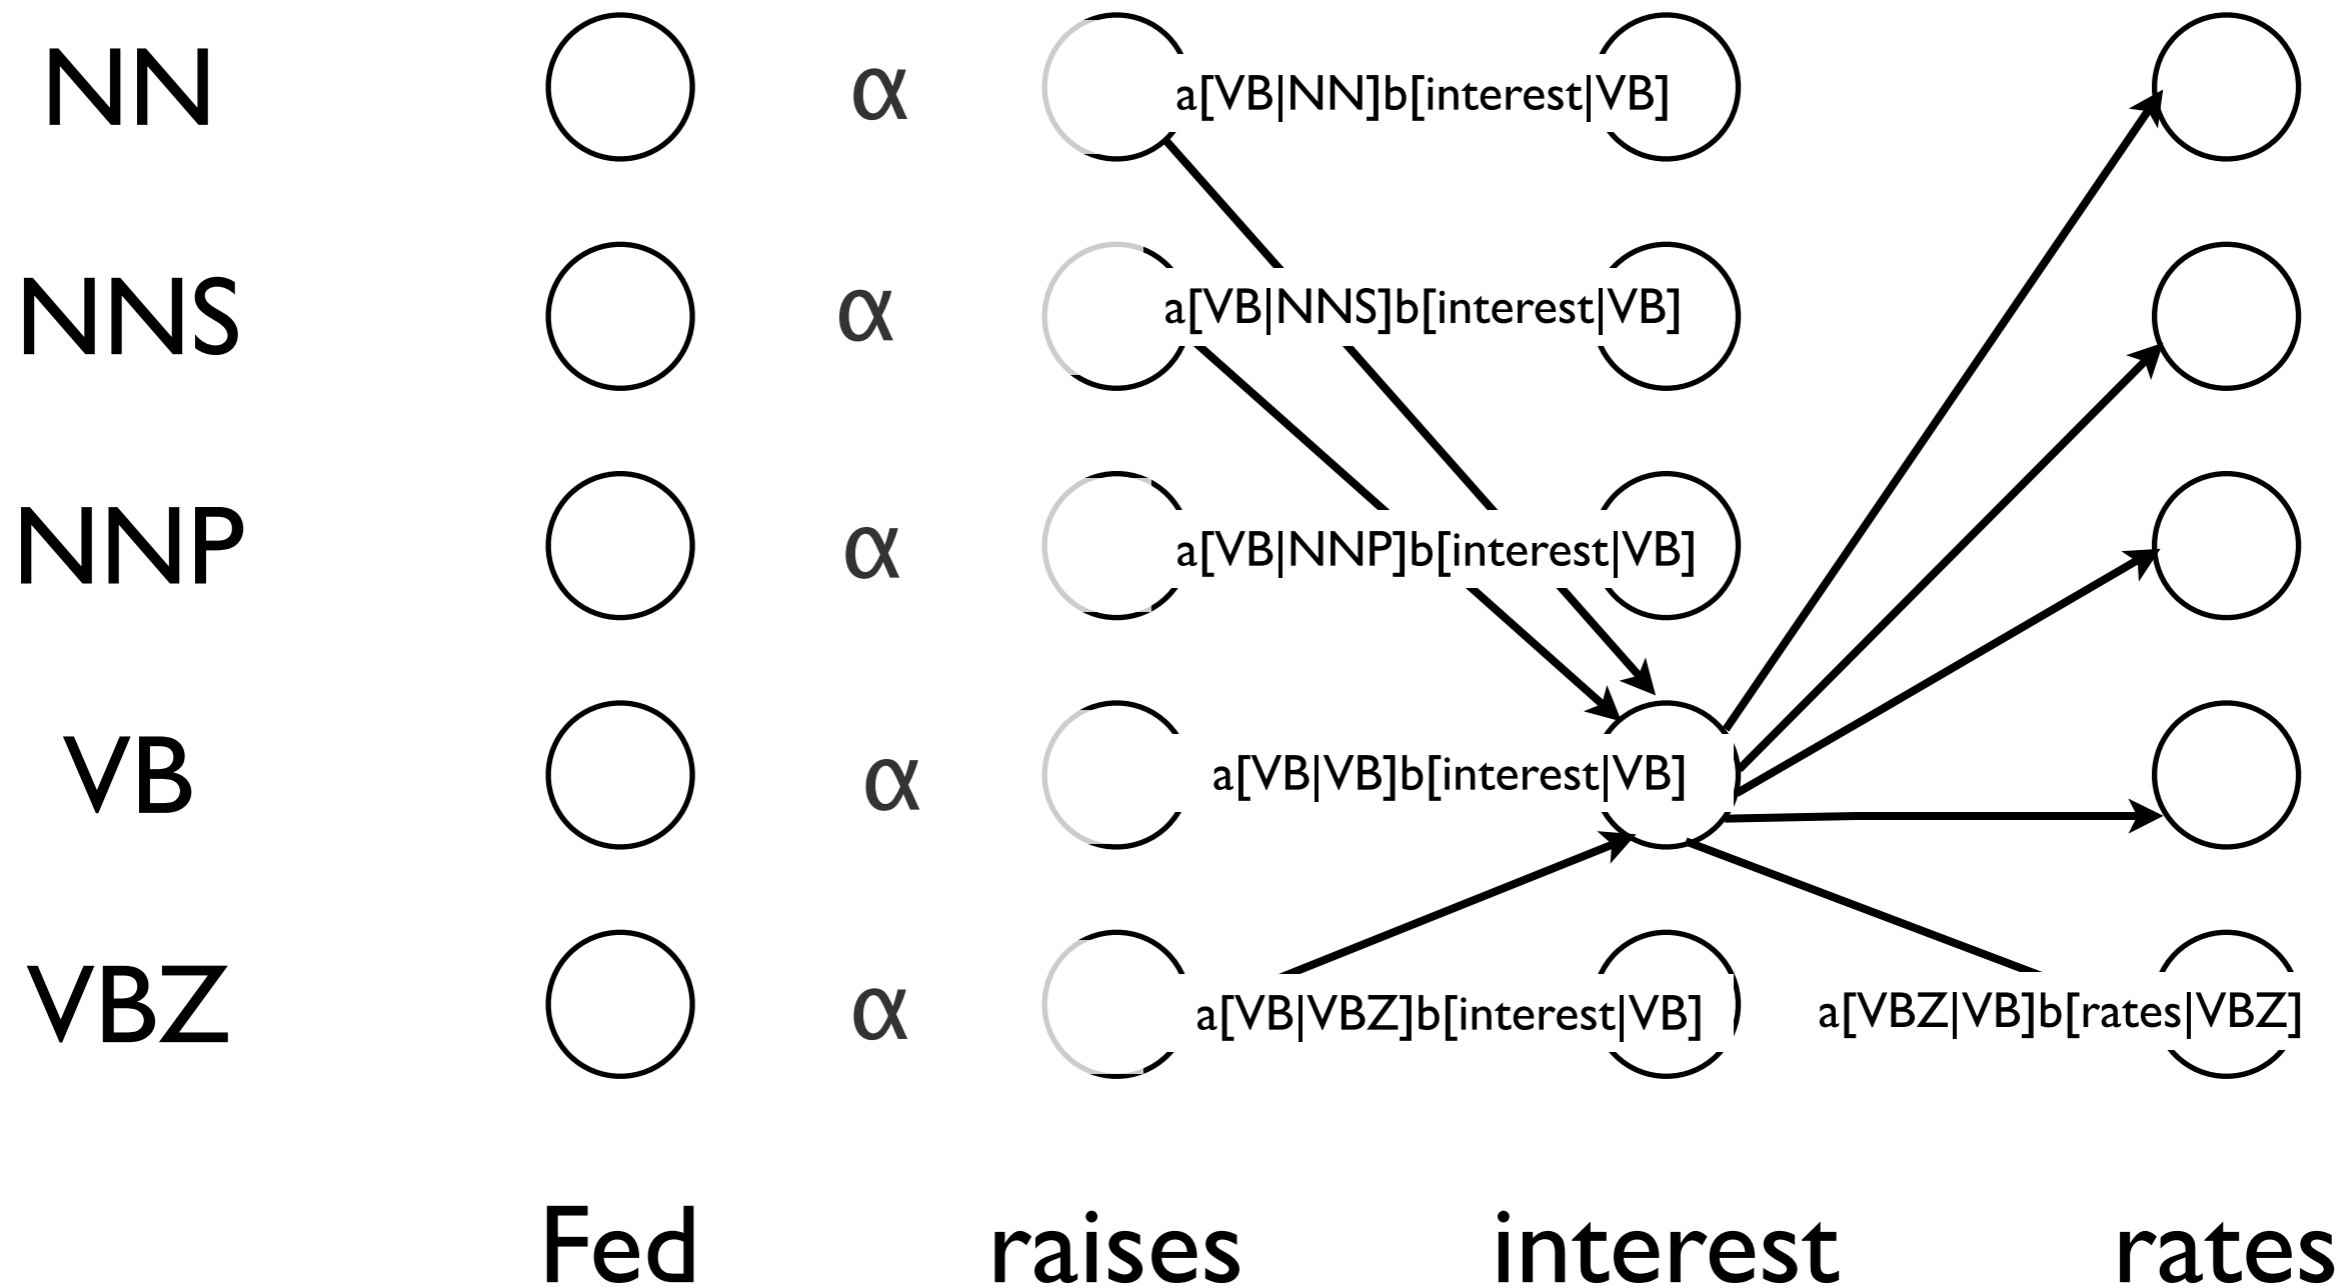

HMM Parameter Estimation

- Supervised
 - Train on tagged text, test on plain text
 - Maximum likelihood (can be smoothed):
 - $a[\text{VBZ} | \text{NN}] = C(\text{NN}, \text{VBZ}) / C(\text{NN})$
 - $b[\text{rates} | \text{VBZ}] = C(\text{VBZ}, \text{rates}) / C(\text{VBZ})$
- Unsupervised
 - Train and test on plain text
 - What can we do?

$$P(o_1 \cdots o_T, x_t = j \mid \mu) = \alpha_j(t)\beta_j(t)$$

$$P(x_t = j \mid O, \mu) = \frac{P(x_t = j, O \mid \mu)}{P(O \mid \mu)} = \frac{\alpha_j(t)\beta_j(t)}{\alpha_{\#}(T)}$$

$$\begin{aligned} P(x_t = i, x_{t+1} = j \mid O, \mu) &= \frac{P(x_t = i, x_{t+1} = j, O \mid \mu)}{P(O \mid \mu)} \\ &= \frac{\alpha_i(t)a[j \mid i]b[o_t \mid j]\beta_j(t+1)}{\alpha_{\#}(T)} \end{aligned}$$

Expectation Maximization (EM)

- Iterative algorithm to maximize likelihood of observed data in the presence of hidden data (e.g., tags)
- Choose an initial model μ
- **Expectation step:** find the expected value of hidden variables given current μ
- **Maximization step:** choose new μ to maximize probability of hidden and observed data
- Guaranteed to increase likelihood
- Not guaranteed to find global maximum

Supervised vs. Unsupervised

Supervised	Unsupervised
Annotated training text	Plain text
Simple count/normalize	EM
Fixed tag set	Set during training
Training reads data once	Training needs multiple passes

Logarithms for Precision

$$P(Y) = p(y_1)p(y_2) \cdots p(y_T)$$

$$\log P(Y) = \log p(y_1) + \log p(y_2) \cdots + \log p(y_T)$$

Increased dynamic range of $[0, 1]$ to $[-\infty, 0]$
